Solution Review: Problem Challenge 3

We'll cover the following

• Rotation Count (medium)

• Solution

• Code

- Time complexity
- Space complexity

• Similar Problems

- Problem 1
- Space complexity

Rotation Count (medium)#

Given an array of numbers which is sorted in ascending order and is rotated 'k' times around a pivot, find 'k'.

You can assume that the array does not have any duplicates.

Example 1:

```
Input: [10, 15, 1, 3, 8]
Output: 2
Explanation: The array has been rotated 2 times.
```

Original array:

1

3

8

10

15

Array after 2 rotations:

10

15

1

3

8

Example 2:

```
Input: [4, 5, 7, 9, 10, -1, 2]
Output: 5
Explanation: The array has been rotated 5 times.
```

Original array:

-1

2

4

5

7

9

10

Array after 5 rotations:

4

5

7

9

10

-1

2

Example 3:

```
Input: [1, 3, 8, 10]
Output: 0
Explanation: The array has not been rotated.
```

Solution#

This problem follows the **Binary Search** pattern. We can use a similar strategy as discussed in [Search in Rotated Array](#).

In this problem, actually, we are asked to find the index of the minimum element. The number of times the minimum element is moved to the right will be equal to the number of rotations. An interesting fact about the minimum element is that it is the only element in the given array which is smaller than its previous element. Since the array is sorted in ascending order, all other elements are bigger than their previous element.

After calculating the `middle`, we can compare the number at index `middle` with its previous and next number. This will give us two options:

- If `arr[middle] > arr[middle + 1]`, then the element at `middle + 1` is the smallest.
- If `arr[middle - 1] > arr[middle]`, then the element at `middle` is the smallest.

To adjust the ranges we can follow the same approach as discussed in [Search in Rotated Array](#). Comparing the numbers at indices `start` and `middle` will give us two options:

- If `arr[start] < arr[middle]`, the numbers from `start` to `middle` are sorted.
- Else, the numbers from `middle + 1` to `end` are sorted.

Code#

Here is what our algorithm will look like:

JavaPython3C++JS

```
1 def count_rotations(arr):
2     start, end = 0, len(arr) - 1
3     while start < end:
4         mid = start + (end - start) // 2
5
6         # if mid is greater than the next element
7         if mid < end and arr[mid] > arr[mid + 1]:
8             return mid + 1
9
10        # if mid is smaller than the previous element
11        if mid > start and arr[mid - 1] > arr[mid]:
12            return mid
13
14        if arr[start] < arr[mid]: # left side is sorted, so the pivot is on right side
15            start = mid + 1
16        else: # right side is sorted, so the pivot is on the left side
17            end = mid - 1
18
19    return 0 # the array has not been rotated
20
21
22 def main():
23     print(count_rotations([10, 15, 1, 3, 8]))
24     print(count_rotations([4, 5, 7, 9, 10, -1, 2]))
25     print(count_rotations([1, 3, 8, 10]))
26
27 main()
28
29
```

Run

Time complexity#

Since we are reducing the search range by half at every step, this means that the time complexity of our algorithm will be $O(\log N)$ where 'N' is the total elements in the given array.

Space complexity#

The algorithm runs in constant space $O(1)$.

Similar Problems#

Problem 1#

How do we find the rotation count of a sorted and rotated array that has duplicates too?

The above code will fail on the following example!

Example 1:

```
Input: [3, 3, 7, 3]
Output: 3
Explanation: The array has been rotated 3 times
```

Original array:

3

3

3

7

Array after 3 rotations:

3

3

7

3

Solution

We can follow the same approach as discussed in [Search in Rotated Array](#). The only difference is that before incrementing `start` or decrementing `end`, we will check if either of them is the smallest number.

JavaPython3C++JS

```
1 def count_rotations_with_duplicates(arr):
2     start, end = 0, len(arr) - 1
3     while start < end:
4         mid = start + (end - start) // 2
5
6         # if element at mid is greater than the next element
7         if mid < end and arr[mid] > arr[mid + 1]:
8             return mid + 1
9
10        # if element at mid is smaller than the previous element
11        if mid > start and arr[mid - 1] > arr[mid]:
12            return mid
13
14        # this is the only difference from the previous solution
15        # if numbers at indices start, mid, and end are same, we can't choose a side
16        # the best we can do is to skip one number from both ends if they are not the smallest number
17        if arr[start] == arr[mid] and arr[end] == arr[mid]:
18            if arr[start] > arr[start + 1]: # if element at start+1 is not the smallest
19                return start + 1
20            if arr[end - 1] > arr[end]: # if the element at end is not the smallest
21                return end
22            end = 1
23
24        # left side is sorted, so the pivot is on right side
25        elif arr[start] < arr[mid] or (arr[start] == arr[mid] and arr[mid] > arr[end]):
26            start = mid + 1
27        else: # right side is sorted, so the pivot is on the left side
28            end = mid - 1
29
30    return 0 # the array has not been rotated
31
32 def main():
```

Run

Time complexity

This algorithm will run in $O(\log N)$ most of the times, but since we only skip two numbers in case of duplicates instead of the half of the numbers, therefore the worst case time complexity will become $O(N)$.

Space complexity#

The algorithm runs in constant space $O(1)$.
