Problem Statement

Given a binary tree and a number 'S', find all paths from root-to-leaf such that the sum of all the node values of each path equals 'S'.

₿

Try it yourself

Try solving this question here:

```
G C++
           Python3
                         JS JS
Java
   class TreeNode:
      def __init__(self, val, left=None, right=None):
        self.val = val
       self.left = left
        self.right = right
 8 def find_paths(root, sum):
      allPaths = []
      # TODO: Write your code here
11
      return allPaths
12
13
14 def main():
15
     root = TreeNode(12)
      root.left = TreeNode(7)
      root.right = TreeNode(1)
      root.left.left = TreeNode(4)
     root.right.left = TreeNode(10)
     root.right.right = TreeNode(5)
      sum = 23
     print("Tree paths with sum " + str(sum) +
23
      ": " + str(find_paths(root, sum)))
25
26
27 main()
                                                                                                                ::3
Run
                                                                                             Save
                                                                                                       Reset
```

Solution

This problem follows the Binary Tree Path Sum pattern. We can follow the same **DFS** approach. There will be two differences:

- 1. Every time we find a root-to-leaf path, we will store it in a list.

 2. We will traverse all paths and will not stop processing after fire.
- 2. We will traverse all paths and will not stop processing after finding the first path.

Code

Here is what our algorithm will look like:

```
Python3
                            G C++
                                         JS JS
  Java
   1 class TreeNode:
         def __init__(self, val, left=None, right=None):
          self.val = val
          self.left = left
          self.right = right
      def find_paths(root, required_sum):
         allPaths = []
        find_paths_recursive(root, required_sum, [], allPaths)
         return allPaths
   11
   12
   14 def find_paths_recursive(currentNode, required_sum, currentPath, allPaths):
         if currentNode is None:
          return
  16
  17
  18
         # add the current node to the path
         currentPath.append(currentNode.val)
        # if the current node is a leaf and its value is equal to required_sum, save the current path
   21
        if currentNode.val == required_sum and currentNode.left is None and currentNode.right is None:
  22
   23
           allPaths.append(list(currentPath))
   24
         else:
   25
           # traverse the left sub-tree
   26
           find_paths_recursive(currentNode.left, required_sum -
   27
                               currentNode.val, currentPath, allPaths)
           # traverse the right sub-tree
           find_paths_recursive(currentNode.right, required_sum -
                               currentNode.val, currentPath, allPaths)
   30
   31
   Run
                                                                                                 Save
                                                                                                          Reset
Time complexity
```

The time complexity of the above algorithm is $O(N^2)$, where 'N' is the total number of nodes in the tree. This is due to the fact that we traverse each node once (which will take O(N)), and for every leaf node, we might

is due to the fact that we traverse each node once (which will take O(N)), and for every leaf node, we might have to store its path (by making a copy of the current path) which will take O(N).

We can calculate a tighter time complexity of O(NlogN) from the space complexity discussion below.

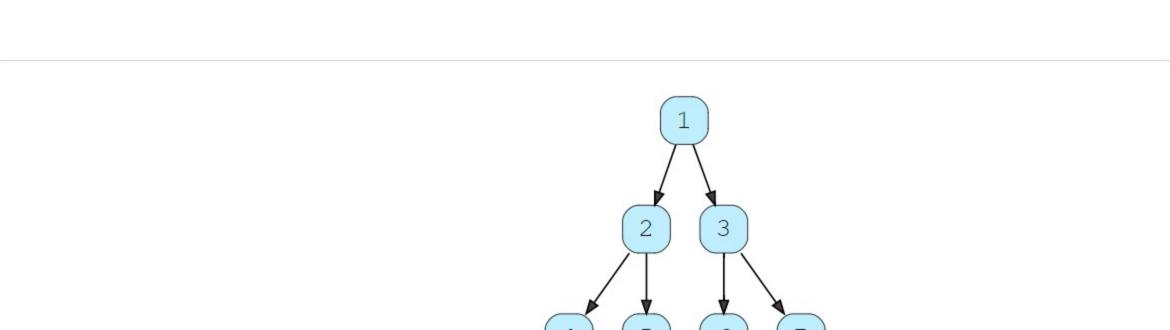

Space complexity#

the given tree is a linked list (i.e., every node has only one child).

If we ignore the space required for the allPaths list, the space complexity of the above algorithm will be

O(N) in the worst case. This space will be used to store the recursion stack. The worst-case will happen when

How can we estimate the space used for the allPaths array? Take the example of the following balanced tree:

Here we have seven nodes (i.e., N=7). Since, for binary trees, there exists only one path to reach any leaf node, we can easily say that total root-to-leaf paths in a binary tree can't be more than the number of leaves. As we know that there can't be more than (N+1)/2 leaves in a binary tree, therefore the maximum number of elements in allPaths will be O((N+1)/2) = O(N). Now, each of these paths can have many nodes in

depth (or height) of a balanced binary tree is O(logN) we can say that, at the most, each path can have logN nodes in it. This means that the total size of the allPaths list will be O(N*logN). If the tree is not balanced, we will still have the same worst-case space complexity.

From the above discussion, we can conclude that our algorithm's overall space complexity is O(N * log N).

Also, from the above discussion, since for each leaf node, in the worst case, we have to copy log(N) nodes to

them. For a balanced binary tree (like above), each leaf node will be at maximum depth. As we know that the

store its path; therefore, the time complexity of our algorithm will also be O(N*logN).

Similar Problems#

Problem 1: Given a binary tree, return all root-to-leaf paths.

Solution: We can follow a similar approach. We just need to remove the "check for the path sum."

Problem 2: Given a binary tree, find the root-to-leaf path with the maximum sum.

Solution: We need to find the path with the maximum sum. As we traverse all paths, we can keep track of the

path with the maximum sum.
